FIG. 6

5 A BUSH AND METHOD OF MANUFACTURING A BUSH

This invention relates to a bush and a method of manufacturing a bush, and more particularly to a method of manufacturing a lined and flanged bush.

10 Blow-down panel bushes are used in aerospace applications and comprise a flanged bush to which a ring of self-lubricating liner is bonded. The component is manufactured and machined on a piece-by-piece basis and is small, standing approximately 4mm high with a rounded rectangular base being approximately 20mm long and 16mm wide.

15 Once the flanged bush has been machined to provide a spigot with a central bore upstanding from the surrounding flange surface, the ring of self-lubricating liner is cut to size and bonded to the flange surface. Great care must be taken to ensure that a constant and consistent pressure is applied to the liner
20 to effect a good adhesive bond between the liner and the flange surface. After bonding is complete, the outer edge of the ring of self-lubricating liner must be trimmed to ensure that no part of the liner protrudes beyond the edge of the flange surface and to ensure that there is no fretting of the liner edge. It is imperative that the liner edge is fully bonded right up to the edge of the flange
25 surface.

With such small pieces of manufacture, it is difficult to maintain a good quality finished product. The manufacturing process is labour-intensive, involves many steps and is also expensive.

- 5 It is an object of the present invention to ameliorate the above-mentioned disadvantages.

Accordingly, one aspect of the present invention provides a method of manufacturing a method of manufacturing a bush from a blank comprising the
10 steps of: providing a blank having a surface to be lined and at least one spigot upstanding from the surface; providing a liner having an aperture; locating the aperture in the liner around the spigot such that the liner lies on the surface; and stamping out the blank around the spigot to provide a lined and flanged bush.

- 15 In order that the present invention may be more readily understood, embodiments thereof will now be described, by way of example, with reference to the accompanying drawings, in which:

Figure 1 is plan view of a flanged bush manufactured in accordance with a
20 method embodying the present invention;

Figure 2 is a cross-section through the bush of Figure 1 taken along line A-A;

Referring to Figure 3, one surface of the billet 10 is machined to leave ten upstanding spigots 2 in a regular array across the surface of the billet 10. A central bore 4 is machined through each of the spigots 2. Further, a pair of registration holes 11 are drilled through the billet 10. The registration holes 11 are provided on different radial axes so as not to be symmetrical with one another about any axis of the billet 10.

Referring now to Figure 4, a sheet of self-lubricating liner 5 is provided into which are cut ten apertures 7 dimensioned to surround, with a clearance gap 8, each of the spigots 2. The apertures 7 in the liner are arranged in the liner sheet so as to register with the spigots 2 on the billet 10.

The liner 5 is also provided with two registration holes 12, which are intended to be aligned with the registration holes 11 on the billet 10 when the spigots 2 pass through their respective apertures 7 in the liner 5.

An adhesive is applied to the liner 5 and the billet surface or the liner 5 may comprise a self-adhesive surface on the surface of the liner 5 facing the surface of the billet 10.

Registration pins 13 are located in registration holes 11 and the liner 5 is laid over the billet 10 lining up the registration holes 12 with the registration pins 13 until the liner sits on the surface of the billet 10 with the spigots 2 protruding through the apertures 7 in the liner 5.

The liner 5 and the billet 10 are pressed together and a consistent and constant pressure is applied over the large surface area of the liner 5 pushing the liner 5 and billet 10 together to ensure a good adhesive bond between the liner 5 and

the billet 10 over the complete surface area of the billet. It is much easier to provide a consistent pressure over the relatively large surface area of a billet 10 containing an array of many spigots 2 then over a ring of liner on a single flanged bush 1.

5

Referring now to Figure 5, the billet 10 and liner 5 are placed in a stamping machine which is arranged to punch out simultaneously ten flanged bushes 1 from the billet 10. In Figure 5, there is a dashed line 14 drawn around each of the spigots 2. This line comprises the punch line 14 or the line of cut which the stamping machine will create, effectively being the outline 14 of each of the flanged bushes 1.

The remaining surface of the billet 10 is punched away from the outlines 14 of the flanged bushes 1 leaving the flanged bushes 1 remaining. The stamping process cuts firstly through the liner 5 and then the material of what will comprise the flange 3 so that there is an element of compression of the liner 5 at the very edge of the flange surface and, indeed, the shearing action of the punching or stamping step creates a mechanical bond between the liner 5 and the flange 3 at the punch line 14, thus ensuring that the liner 5 is fully bonded around the edge of the flange to the flange.

The stamping operation means that the previous manufacturing steps, used to produce a conventional panel bush, of trimming the liner 5 around the edge of the flange and removing the excess glue from between the liner and the edge of the flange are no longer required. The shearing action of the stamping or punching step means that the liner is very neatly finished with respect to the edge of the flange 3 and, as shown in Figure 6, particularly when a metal mesh is used in the liner 5, there is an element of a mechanical bond 15 between the

liner 4 and the flange 3 at the point of contact between the liner 5 and the flange 3 around the edge of the flange 3.

Another advantage of the use of the stamping technique where the liner has
5 been pre-applied to the billet is the fact that the pressure can be applied to the liner more consistently over the large surface area of the billet 10 containing many bushes 1 as opposed to just on a single bush 1.

There is an additional advantage in that manufacturing the bushes from a
10 reasonably sized, if not large, billet, is far preferable from a handling point of view to manufacture the bushes on an individual piece-by-piece basis.

In the present specification "comprises" means "includes or consists of" and
"comprising" means "including or consisting of".

CLAIMS:

1. A method of manufacturing a bush from a blank comprising the steps of:
providing a blank having a surface to be lined and at least one spigot
5 upstanding from the surface;
providing a liner having an aperture;
locating the aperture in the liner around the spigot such that the liner lies on the
surface; and
stamping out the blank around the spigot to provide a lined and flanged bush.
10
2. A method according to Claim 1, wherein the step of stamping includes
the step of cutting through the liner and then into at least part of the blank.
3. A method according to Claim 1 or 2, wherein the step of stamping
15 comprises cutting completely through the blank.
4. A method according to any preceding claim, wherein the blank is
stamped from the side of the blank provided with the liner.
- 20 5. A method according to any preceding claim, wherein the liner is bonded
to the surface prior to stamping.
6. A method according to Claim 5, wherein pressure is applied to the liner
prior to stamping to assist consistent bonding of the liner to the surface.
25
7. A method according to any preceding claim, wherein the liner around
the spigot is spaced apart from the spigot by a clearance gap.

8. A method according to any preceding claim, wherein a plurality of spigots are provided on the blank and the liner is provided with at least a corresponding number of apertures, wherein the apertures are located around respective spigots such that the liner lies on the surface and the step of
5 stamping out the blank around the spigot to provide a flanged bush is carried out simultaneously for all the spigots so as to provide a plurality of lined and flanged bushes from one stamping operation.
9. A method according to Claim 8, wherein the spigots are provided on the
10 blank in a regular array.
10. A method according to any preceding claim, wherein the blank is machined to provide the or each spigot, the or each spigot having a central bore machined therein.
15
11. A method according to any preceding claim, wherein the blank is a billet machined from a bar of material.
12. A method according to any preceding claim, wherein the stamping step
20 provides a mechanical bond between the edge of the liner and the edge of the flange for the or each flanged bush.
13. A method of manufacturing a bush substantially as hereinbefore described with reference to and as shown in the accompanying drawings.
25
